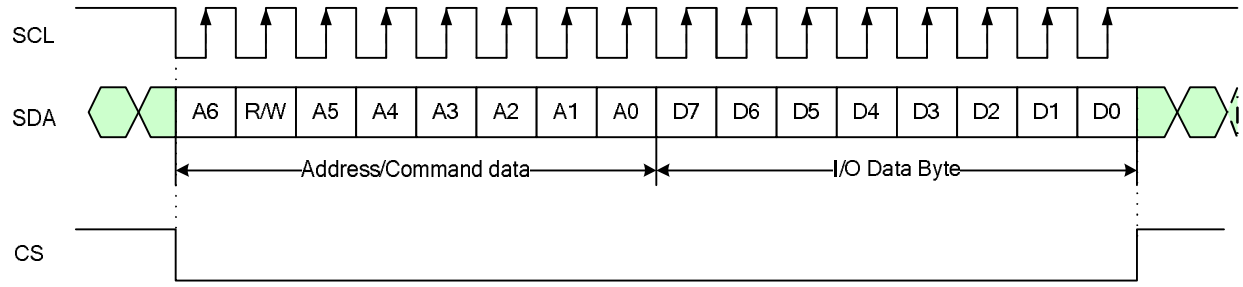
6.1 Timing chart



1. Each serial command consists of 16 bits of data which is loaded one bit a time at the rising edge of serial clock SCL.
2. Command loading operation starts from the falling edge of CS and is completed at the next rising edge of CS.
3. The serial control block is operational after power on reset, but commands are established by the VSYNC signal. If command is transferred multiple times for the same register, the last command before the VSYNC signal is valid.
4. If less than 16 bits of SCL are input while CS is low, the transferred data is ignored.
5. If 16 bits or more of SCL are input while CS is low, the previous 16 bits of transferred data before the rising edge of CS pulse are valid data.
6. Serial block operates with the SCL clock.
7. Serial data can be accepted in the standby (power save) mode.

	y	θ =0°	(0.28)	(0.33)	(0.38)		

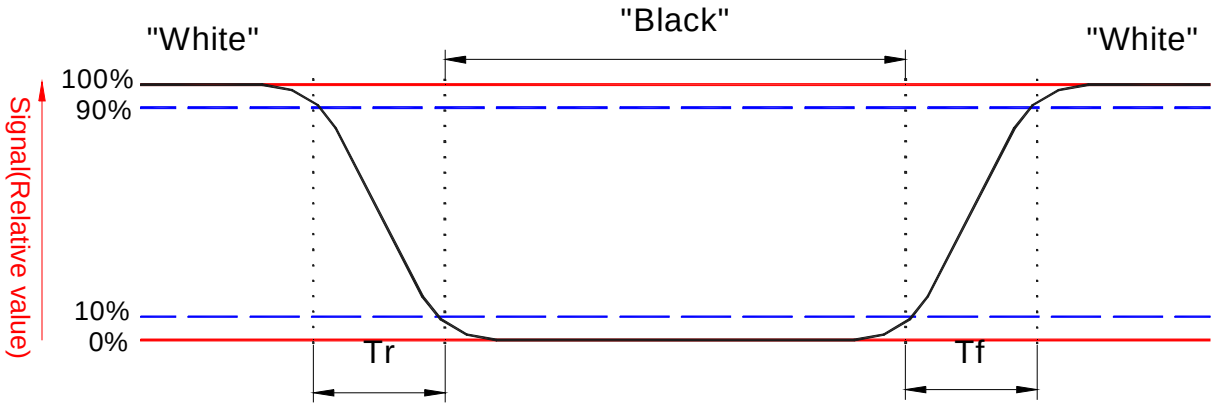
Note 1. Ambient temperature =25℃.

Note 2. To be measured in the dark room.

Note 3.To be measured on the center area of panel with a field angle of 1°by Topcon luminance meter BM-7, after 10 minutes operation.

Note 4. Definition of response time:

The output signals of photo detector are measured when the input signals are changed from “black” to “white”(falling time) and from “white” to “black”(rising time), respectively.



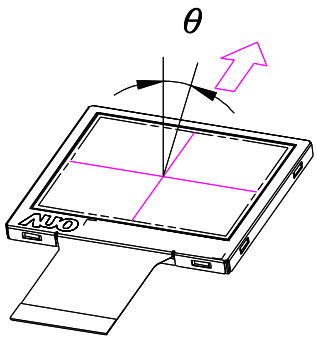
The response time is defined as the time interval between the 10% and 90% of amplitudes. Refer to figure as below.

Note 5. Definition of contrast ratio:
Contrast ratio is calculated with the following formula.

$$\text{Contrast ratio (CR)} = \frac{\text{Photo detector output when LCD is at “White” state}}{\text{Photo detector output when LCD is at “Black” state}}$$

Note 6. White $Vi=V_{i50} \mp 1.5V$
Black $Vi=V_{i50} \pm 2.0V$
“±” Means that the analog input signal swings in phase with COM signal.
“∓” Means that the analog input signal swings out of phase with COM signal.
V_{i50} : The analog input voltage when transmission is 50%
The 100% transmission is defined as the transmission of LCD panel when all the input terminals of module are electrically opened.

Note 7. Definition of viewing angle:
Refer to figure as below.



Note 8. Measured at the center area of the panel when all the input terminals of LCD panel are electrically opened with LED current = 25 mA.

2. Power on/off sequence

The register setting of standby mode disabling / enabling is used to control the build-in power on / off sequence.

2.1 Power on (Standby Disabling)

After VDD power on reset, VSYNC/HSYNC/DCLK/DATA can be input, and serial control interface is also operational. The LCD driver is in default standby mode after VDD power-on, and setting register STB to '1' to disable the standby mode is required for normal operation. When the standby mode is disabled, a build-in power on sequence is started. The LCD positive and negative power supplies VGH/VGL are pumped first, and followed by the LED power VLED. Please refer to Fig.10 for the detail timing of power on sequence.

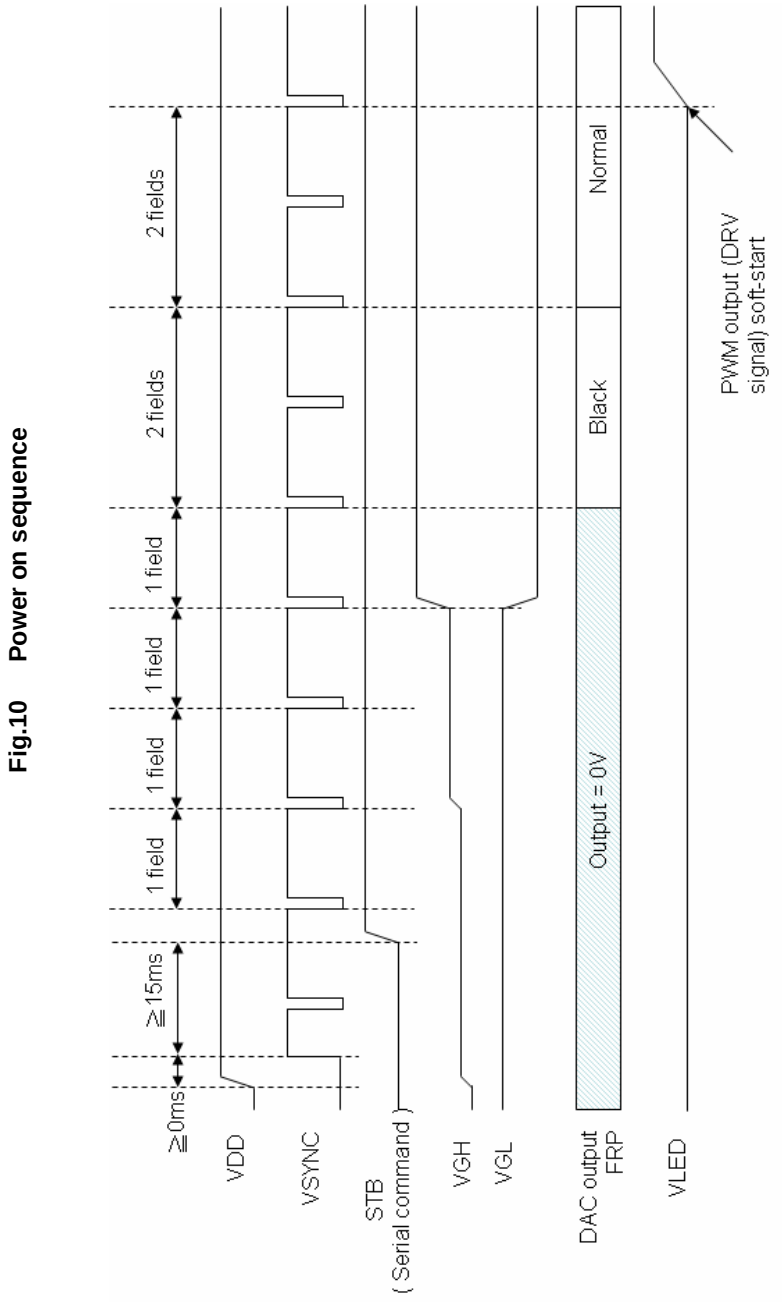

Fig.10 Power on sequence

3.2 Power off (Standby Enabling)

When the register STB is set to '0' to enable standby mode, a build-in power off sequence is started. Please refer to Fig.11 for the detail timing of power off sequence.
