	L Level	$V_{IL}$	GND	-	$0.3 \times VDDIO$	V

Note 1: A build-in power on reset circuit for VDD and VDDIO is provided within the integrated LCD driver IC. The LCD module is in power save mode in default, and a standby releasing is required after VDDIO power on through serial control. Please refer to the register STB setting for detail.

Note 2: The power supply of digital interface, VDDIO, is for the 1.8V digital interface requirement in the future. These digital signals are DCLK, HSYNC, VSYNC, D7~D0, CS, SDA and SCL. If the digital interface level is 3.3V, please short the power pin VDD and VDDIO to 3.3V. In other words, no matter the voltage level of VDDIO is 1.8V or 3.3V, the voltage level of VDD needs to be kept 3.3V.

Note 1: Test Condition: 8colorbar+Grayscale pattern, UPS051 mode, DCLK=27MHz, Frame rate: 60Hz, other registers are default setting.

Note 2:  $V_{GH}$  and  $V_{GL}$  are output voltages of integrated LCD driver IC.

Note 3: The brightness of LCD panel could be adjusted by the adjustment of the AC component of VCOM.

Note 4:  $V_{CDC}$  could be adjusted, so as to minimize flicker and maximum contrast on each module.

#### 5.3.1 CCIR656 decoding

- FF 00 00 < XY > signals are involved with HSYNC, VSYNC and Field

- <XY> encode following bits:

F=field select : F=0 for field 1, F=1 for field 2;

V=1 during vertical blanking

H=0 at SAV , H=1 at EAV ,

P3-P0=protection bits :

$P3 = V \oplus H$     $P2 = F \oplus H$     $P1 = F \oplus V$     $P0 = F \oplus V \oplus H$     $\oplus$ : represents the exclusive-OR function

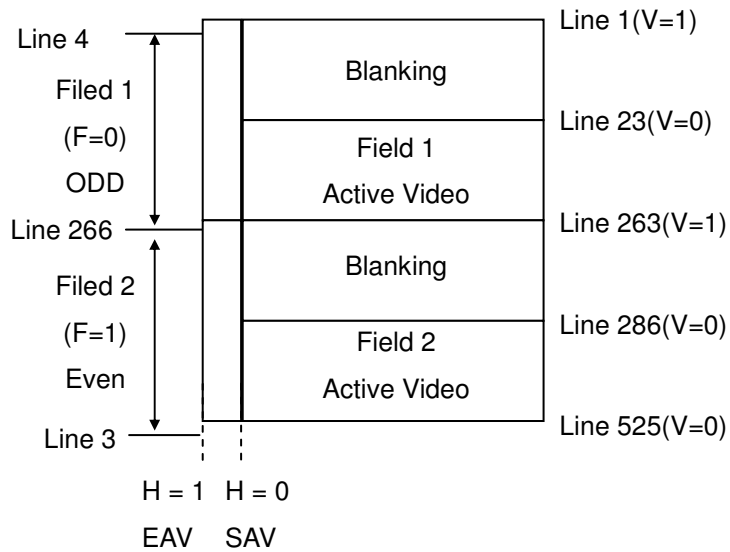

- Control is provided through “End of Video” (EAV) and “Start of Video” (SAV) timing references.
- Horizontal blanking section consists of repeating pattern 80 10 80 10

SCL pulse high width	$t_{W1H}$	50	-	-	ns
CS pulse high width	$t_{W2}$	400	-	-	ns

### 6.1 Timing chart

- Each serial command consists of 16 bits of data which is loaded one bit a time at the rising edge of serial clock SCL.
- Command loading operation starts from the falling edge of CS and is completed at the next rising edge of CS.
- The serial control block is operational after power on reset, but commands are established by the VSYNC signal. If command is transferred multiple times for the same register, the last command before the VSYNC signal is valid.
- If less than 16 bits of SCL are input while CS is low, the transferred data is ignored.
- If 16 bits or more of SCL are input while CS is low, the previous 16 bits of transferred data before the rising edge of CS pulse are valid data.
- Serial block operates with the SCL clock.
- Serial data can be accepted in the standby (power save) mode.

for example:

LED\_ON\_RATIO is "1001", and LED\_ON\_CYCLE is "0111", then:

Cycle =  $16 * 8 = 128$ (HSYNC)

Enable =  $8 * ((10/16) * 16) = 80$ (HSYNC)

Disable =  $8 * (16 - (10/16) * 16) = 48$ (HSYNC) → 62.5% on

Note 4. Definition of response time:

The output signals of photo detector are measured when the input signals are changed from “black” to “white”(falling time) and from “white” to “black”(rising time), respectively.

The response time is defined as the time interval between the 10% and 90% of amplitudes. Refer to figure as below.

## 2. Power on/off sequence

The register setting of standby mode disabling / enabling is used to control the build-in power on / off sequence.

### 2.1 Power on (Standby Disabling)

After VDD/VDDIO power on reset, VSYNC/HSYNC/DCLK/DATA can be input, and serial control interface is also operational. The LCD driver is in default standby mode after VDD/VDDIO power-on, and setting register STB to '1' to disable the standby mode is required for normal operation. When the standby mode is disabled, a build-in power on sequence is started. The LCD positive and negative power supplies VGH/VGL are pumped first, and followed by the LED power VLED. Please refer to Fig.10 for the detail timing of power on sequence.

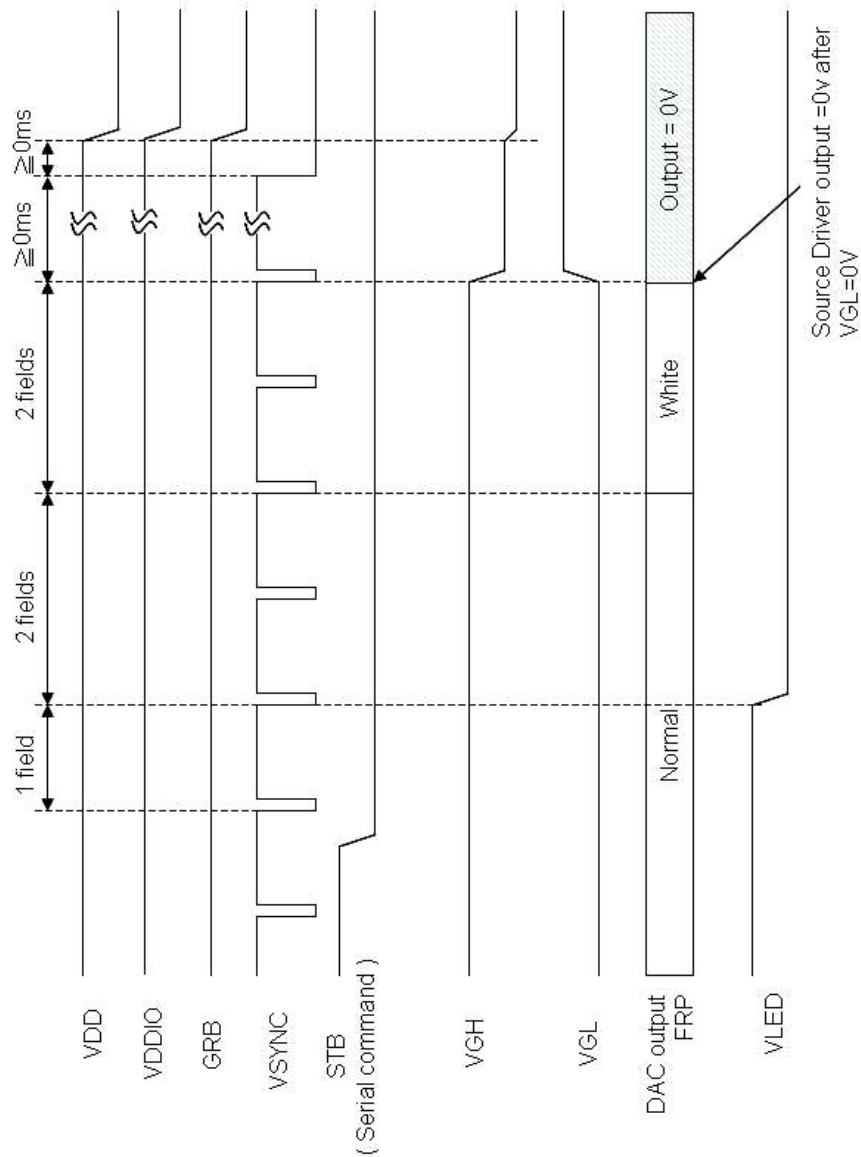

Fig.10 Power on sequence

### 3.2 Power off (Standby Enabling)

When the register STB is set to '0' to enable standby mode, a build-in power off sequence is started. Please refer to Fig.11 for the detail timing of power off sequence.

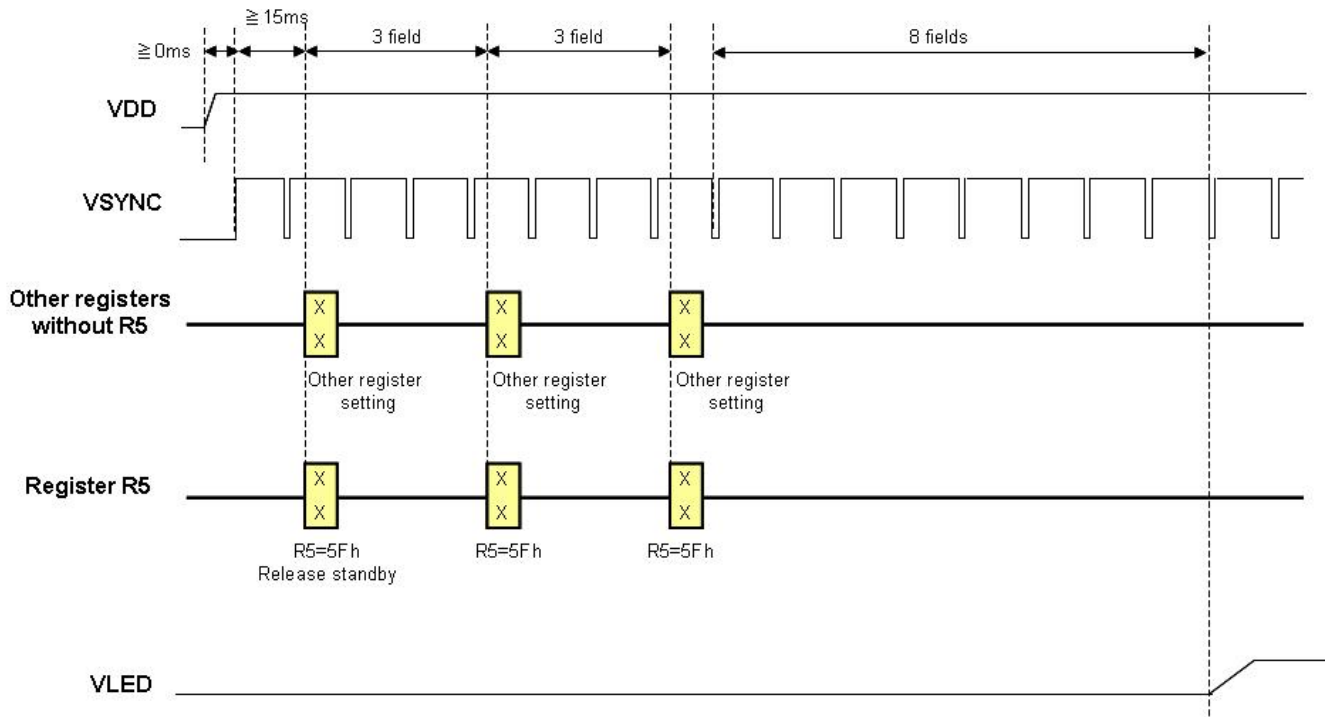

Fig.11 Power off sequence

### 3. Recommended power on/off serial command settings

Since the LCD driver default is in standby mode, so setting register R5: STB to '1' to disable standby mode is required for normal operation. The standby mode disabling method must follow Fig.12 sequence during power on. Furthermore, the three times other register setting must be same.

**Fig. 12 LCD serial command setting during power on**

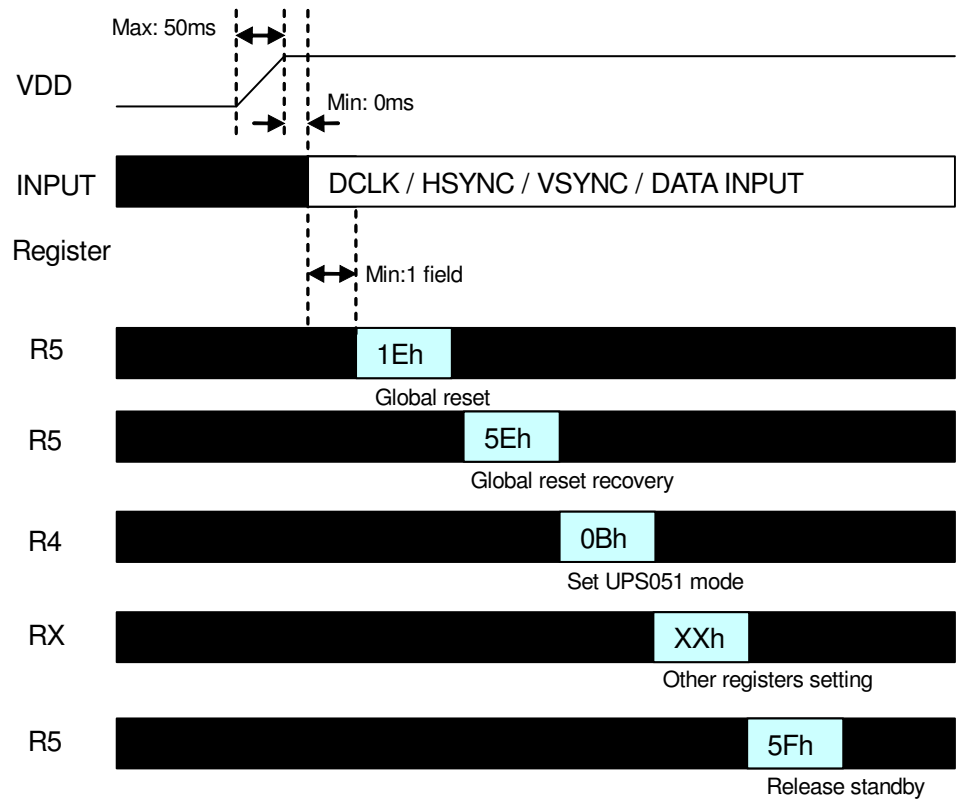

Note 1: Under different input timing, the register R0 and R4 are required setting. Please reference next section.
